Final

Function

I chose to make a treaded wheel system. It will also operate utilizing tank drive steering. It will use 2 cylindrical sections with extruded texture to help with gaining traction on virtually any environment. It will be powered by 2 motors per side to rotate the outer rubberized section, the motors will be synchronized to the same direction and speed to keep tension and make sure there isn't any unexpected behavior.

Pictures

Refinements

With more time, I would look into more track geometry to determine what would give the biggest benefit to traction and efficiency for movement.
